Business Applications with Agentic AI

Course Outline

Consider the following business questions:

- How can organizations build AI systems that not only generate text but also plan, reason, and take actions autonomously across complex workflows?
- How can AI agents leverage tools, memory, and reasoning to automate multi-step business processes such as research, customer support, and operations?
- How can organizations manage and control the performance of autonomous AI agents deployed in real-world workflows?

These questions reflect real-world challenges where Agentic AI extends the capabilities of Generative AI and Large Language Models (LLMs) beyond content generation into intelligent, goal-driven systems. Through this course, you'll gain the knowledge to understand how AI agents perceive their environment, reason over tasks, interact with tools, and adapt dynamically laying the foundation for building scalable, enterprise-ready agentic solutions.

Overview

This course is designed to provide a strong conceptual and practical understanding of Agentic AI and its business applications, without requiring deep expertise in AI research or systems engineering. It explains how large language models evolve into autonomous agents by incorporating planning, reasoning, memory, grounding, validation, and external
