Not the ReACT you're thinking about!!

Table of contents:

1. Introduction
2. Basics of AI agent
3. Where ReACT falls under all of this
4. ReACT usage in more practical terms
5. Code implementing ReACT from scratch
6. References

1.Introduction

Large Language Models(LLM) represent big leap from earlier AI models but it still has limitations in fully mimicking certain aspects of human intelligence, one important area where they fall behind is reasoning and self-improvement — qualities humans naturally exhibit before reaching a conclusion.

To overcome this issue the concept of AI agents can be helpful particularly LLM agents. Various groups are now developing what the next generation of AI applications will look like, with an increased usage of compound AI systems like Retrieval-Augmented Generation (RAG).

Agentic systems introduce elements like planning, feedback loops, reflection, and other control structures that tap into the model's inherent reasoning capabilities to accomplish tasks end-to-end.

AI agents are autonomous entities designed to perceive their environment, make decisions, and take actions to achieve specific goals. They leverage a range of technologies to interact with their surroundings and execute tasks efficiently.
