

Great Learning

2-3 minutes

QUICK RECAP

In the previous course, prompt engineering techniques were explored, along with how Retrieval-Augmented Generation (RAG) enables LLMs to produce context-aware responses by injecting relevant external information into the model.

WEEK OVERVIEW

This week focuses on introducing Agentic AI and explaining why AI agents are needed beyond traditional LLM-based approaches. The sessions will cover how LLMs function as the reasoning core of agents, how agents interact with their environments, and how grounding and validation improve reliability. The week concludes with a hands-on introduction to building simple AI agents using modern frameworks.

The following topics will be covered:

- The Need for AI Agents (Agentic AI vs Traditional Approaches, The Role of LLMs)
- Types of Agents (reactive agents, proactive agents, and interactive agents)
- Agent Environments (Static vs. Dynamic, Single-Agent vs. Multi-Agent, Deterministic vs. Stochastic)
- Grounding and Validation
- Building Simple Single-agent Systems

LEARNING OBJECTIVES

By the end of this module, you will be able to:

- Differentiate between traditional AI approaches and Agentic AI, and explain how LLMs enable autonomous and adaptive agent behavior.
- Classify and assess different types of AI agents (reactive, proactive, interactive) and their suitability for business problem-solving.
- Analyze agent environments (static vs. dynamic, single-agent vs. multi-agent, deterministic vs. stochastic) to identify appropriate deployment contexts.
- Apply grounding and validation techniques to improve reliability, alignment, and trustworthiness of agent outputs.
- Design and experiment with single-agent systems to solve business problems.
